Abstract—Smart traffic-light systems are being studied as a way to reduce waiting time and respond more quickly to changing road conditions. Traditional traffic lights follow fixed timers, which cannot react when roads suddenly become congested. Recent systems utilize cameras and artificial intelligence (AI) to estimate vehicle density and adaptively adjust light timings. This paper reviews existing AI-based signal control strategies, contrasts cloud-based processing with local edge computing, and identifies key gaps regarding emergency vehicle routing.

Index Terms—Smart Traffic Lights, Edge AI, Computer Vision, Adaptive Traffic Signal Control, Emergency Routing.

I. LITERATURE REVIEW

Smart traffic-light systems are being studied as a way to reduce waiting time and respond more quickly to changing road conditions. Traditional traffic lights usually follow fixed timers. They are simple and inexpensive, but they cannot easily react when one road suddenly becomes crowded. Recent systems use cameras and artificial intelligence (AI) to estimate how many vehicles are present and then adjust the lights. For beginners, the main idea is simple: instead of changing lights only according to a clock, the system uses information from the road. Research reviews also show growing interest in AI-based traffic signal control and its possible benefits for changing traffic conditions [1].

Cloud-based AI systems send camera information to a central server for processing. This can provide strong computing power, but it depends on an internet connection and can introduce communication delay. Local smart-camera systems move some processing closer to the road. This can reduce the amount of information that must be sent over the internet and may allow faster decisions. A small local computer can examine camera input and send a short instruction to the traffic-light controller. Machine-vision research has also explored using camera-based vehicle information to adapt traffic-light timing [2].

The three main system implementations can be compared using three core measures: decision latency, internet data usage, and initial setup cost, as outlined in Table I.

TABLE I
COMPARISON OF TRAFFIC LIGHT SYSTEMS

System Type	Decision Time	Data Usage	Setup Cost
Basic Timed Lights	30.0 s	Zero	\$200
Cloud AI Systems	2.0 s	High	\$2,500
Local Smart Cameras	0.5 s	Low	\$1,200

II. SIMPLE SYSTEM ARCHITECTURE

The proposed architecture follows four steps:

- 1) **Street Cameras**: Capture live video of traffic conditions.
- 2) **Smart Pole Computers**: Perform local video processing and make a quick traffic control decision.
- 3) **City Cloud Server**: Selected summary information is forwarded for central storage and wider analysis.
- 4) **Traffic Lights**: Receive the instruction and change signal modes accordingly.

The system flow is illustrated in Figure 1.

Fig. 1. Overview of the four-step System Architecture flow.

III. RESEARCH GAP

Existing traffic systems can work well for regular daily traffic, especially when traffic patterns are predictable. However, an important emergency problem remains: many systems do not have a built-in way to automatically clear a path for a speeding ambulance. This creates a need for a smart traffic system that can detect an emergency vehicle and quickly coordinate nearby signals to create a clear route.
